Sample Practice Problem and Solution

Question:

A 50.0 g sample of ice at 0°C is heated until it melts and then warmed to 20°C. The heat of fusion for ice is 6.00 kJ/mol, and the specific heat capacity of liquid water is 4.18 J/g°C. What is the total heat absorbed during this process?

- A) 334 J
- B) 502 J
- C) 1250 J
- D) 1500 J

Solution:

- Calculate moles of ice:

Molar mass of water ? 18. g/mol

Moles of ice = 50.0 g / 18. g/mol ? 2.78 mol

- Heat to melt ice (fusion):

$$Q_1 = ?H_f \times \text{moles} = 6.00 \text{ kJ/mol} \times 2.78 \text{ mol} = 16.7 \text{ kJ} = 16,700 \text{ J}$$

- Heat to warm water from 0°C to 20°C:

$$Q_2 = \text{mass} \times \text{specific heat} \times \text{temperature change}$$

$$Q_2 = 50.0 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times 20^\circ\text{C} = 50.0 \times 4.18 \times 20 = 4180 \text{ J}$$

- Total heat absorbed:

$$Q_{\text{total}} = Q_1 + Q_2 = 16,700 \text{ J} + 4180 \text{ J} = 20,880 \text{ J}$$

Answer:

None of the options exactly match, but if the options are approximate, D) 1500 J is too low, B) 502 J is too low, C) 1250 J is too low, and A) 334 J is too low. Given the calculations, the closest approximate value is about 21,000 J, indicating a potential typo in options or a need for units.

Note: The question should have options around 20,000 J for accuracy, but as per this calculation, the process demonstrates how to approach such problems.

Using Practice Problems for Effective Learning

To maximize the benefit of thermochemistry MCQs, students should:

- Attempt a variety of questions regularly: This builds familiarity with different problem types.

QuestionAnswer Which of the following best describes an exothermic reaction in thermochemistry? An exothermic reaction releases heat to the surroundings, resulting in a negative ΔH value. In a calorimetry experiment, if 50 g of water absorbs 500 J of heat, what is the change in temperature? (Specific heat capacity of water = $4.18 \text{ J/g}^\circ\text{C}$) ?
 $T = 500 \text{ J} / (50 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C})$?

2.39°C Which statement is true about standard enthalpy of formation (ΔH_f°)? It is the change in enthalpy when one mole of a compound is formed from its elements in their standard states. Given the reaction: $\text{N}_2 + 3\text{H}_2 \rightarrow 2\text{NH}_3$, which of the following indicates an exothermic process? A negative ΔH for the reaction, indicating heat is released during ammonia formation. How does increasing temperature generally affect the spontaneity of an endothermic reaction? Increasing temperature can make an endothermic reaction more spontaneous if ΔS is positive, considering $\Delta G = \Delta H - T\Delta S$. What is the primary purpose of Hess's Law in thermochemistry calculations? To determine the overall enthalpy change for a reaction by combining multiple thermochemical equations. In a reaction with $\Delta H = +100 \text{ kJ}$ and $\Delta S = +200 \text{ J/K}$, at what temperature would the reaction become spontaneous? When $\Delta G = 0$, $T = \Delta H / \Delta S = (100,000 \text{ J}) / (200 \text{ J/K}) = 500 \text{ K}$. Which of the following is NOT a standard condition for thermochemical measurements? A standard temperature of 25°C (298 K) and 1 atm pressure. If a reaction has an enthalpy change of $\Delta H = -50 \text{ kJ}$ and an entropy change of $\Delta S = 150 \text{ J/K}$, at what temperature does it become non-spontaneous? The reaction becomes non-spontaneous when $\Delta G > 0$; $T = \Delta H / \Delta S = (-50,000 \text{ J}) / (150 \text{ J/K}) = -333.33 \text{ K}$, which is physically meaningless, so it remains spontaneous at all positive temperatures. Which of the following best explains the concept of heat capacity in thermochemistry? Heat capacity is the amount of heat required to raise the temperature of a substance by 1°C or 1 K .

Typical Questions in a Chemistry B Thermochemistry Packet

Students working through thermochemistry packets often encounter various question types, such as conceptual questions, calculation problems, and application-based scenarios. Here, we will break down common question formats and provide detailed answers.

- Calculating Enthalpy Changes from Heat Measurements

Question Example:

A 50.0 g sample of ice at 0°C is melted in a calorimeter. If the temperature of the calorimeter increases from 0°C to 5°C during the process, and the calorimeter's heat capacity is $100 \text{ J}/^\circ\text{C}$, what is the enthalpy change of melting the ice?

Answer Breakdown:

- Step 1: Calculate the heat absorbed by the calorimeter:

$$q_{\text{calorimeter}} = C_{\text{calorimeter}} \times \Delta T = 100 \, \text{J/}^{\circ}\text{C} \times 5 \, ^{\circ}\text{C} = 500 \, \text{J}$$

- Step 2: Recognize that the heat absorbed by the calorimeter is equal in magnitude to the heat required to melt the ice (assuming no heat loss).

$$q_{\text{ice}} = 500 \, \text{J}$$

- Step 3: Convert heat to molar basis:

Number of moles of ice:

$$\text{Moles} = \frac{50.0 \, \text{g}}{18.015 \, \text{g/mol}} \approx 2.78 \, \text{mol}$$

- Step 4: Calculate ΔH for melting per mole:

$$\Delta H_{\text{melt}} = \frac{q_{\text{ice}}}{\text{moles}} = \frac{500 \, \text{J}}{2.78 \, \text{mol}} \approx 180 \, \text{J/mol}$$

Conclusion:

The enthalpy of fusion (melting) for ice under these conditions is approximately +180 J/mol, indicating an endothermic process.

- Applying Hess's Law to Find Enthalpy Changes

Question Example:

Given the following reactions:

- $\text{C} + \text{O}_2 \rightarrow \text{CO}_2 \quad \Delta H = -393.5 \, \text{kJ}$

Calculate the ΔH for the formation of CO from C and O₂.

Answer Breakdown:

- Step 1: Recognize that the formation of CO from C and O₂ can be related to the given reactions.

- Step 2: Write the target reaction:

- Step 3: Reverse reaction 2 to get:

- Step 4: Add this reversed reaction to reaction 1:

plus

- Step 5: The sum yields:

- Step 6: Simplify to the target reaction:

- Step 7: Sum the enthalpy changes:

$$\Delta H = -393.5 \text{ kJ} + 110.5 \text{ kJ} = -283 \text{ kJ}$$

Result:

The enthalpy change for forming CO from C and O₂ is -283 kJ.

- Interpreting Standard Enthalpy of Formation Data

Question Example:

Using standard enthalpies of formation, determine the enthalpy change for the reaction:

Given:

- $\Delta H^\circ_f (\text{CH}_4) = -74.8 \text{ kJ/mol}$
- $\Delta H^\circ_f (\text{CO}_2) = -393.5 \text{ kJ/mol}$
- $\Delta H^\circ_f (\text{H}_2\text{O, liquid}) = -285.8 \text{ kJ/mol}$

Answer Breakdown:

- Step 1: Write the enthalpy change formula:

$$\Delta H^\circ_{\text{rxn}} = [\sum \Delta H^\circ_f (\text{products})] - [\sum \Delta H^\circ_f (\text{reactants})]$$

- Step 2: Calculate the total for products:

$$(-393.5) + 2 \times (-285.8) = -393.5 - 571.6 = -965.1 \text{ kJ}$$

- Step 3: Calculate the total for reactants:

$$-74.8 + 2 \times 0 \text{ (since O}_2 \text{ in its elemental form has } \Delta H^\circ_f = 0) = -74.8 \text{ kJ}$$

- Step 4: Find the $\Delta H^\circ_{\text{rxn}}$:

$$-965.1 - (-74.8) = -890.3 \text{ kJ}$$

Conclusion:

The reaction releases approximately 890.3 kJ of energy, indicating an exothermic process.

In-Depth Review of Key Concepts with Answers

1. Calculating Heat Transfer in Calorimetry

Question:

A 50.0 g sample of water is heated from 25°C to 75°C. How much heat energy is absorbed? (Specific heat capacity of water = 4.18 J/g°C)

Answer:

Using the formula:

$$q = mc\Delta T$$

where:

- $m = 50.0\text{ g}$
- $c = 4.18\text{ J/g}^\circ\text{C}$
- $\Delta T = 75^\circ\text{C} - 25^\circ\text{C} = 50^\circ\text{C}$

Calculation:

$$q = 50.0\text{ g} \times 4.18\text{ J/g}^\circ\text{C} \times 50^\circ\text{C}$$

$$q = 50.0 \times 4.18 \times 50 = 10,450\text{ J}$$

Result:

The water absorbs 10,450 Joules of heat energy.

2. Applying Hess's Law

Question:

Given the following reactions:

- $\text{C} + \text{O}_2 \rightarrow \text{CO}_2$ ($\Delta H = -393.5\text{ kJ}$)
- $\text{CO} + \frac{1}{2} \text{O}_2 \rightarrow \text{CO}_2$ ($\Delta H = -283\text{ kJ}$)

Find ΔH for the reaction:

Answer:

Using Hess's Law, arrange the reactions to cancel out common terms:

From the second reaction:

Reversing it:

Now, add this to the first reaction:

Sum:

Simplify:

Total enthalpy change:

$$(-393.5 \text{ kJ} + 283 \text{ kJ}) = -110.5 \text{ kJ}$$

Result:

$\Delta H = -110.5 \text{ kJ}$ for the formation of CO from C and O_2 .

3. Bond Enthalpy Calculations

Question:

Calculate the approximate enthalpy change for the reaction:

Bond	Enthalpy (kJ/mol)
C-H	412
C=O	799
O=O	498

Answer:

Step 1: Break all bonds in reactants:

- 4 C-H bonds: $(4 \times 412 = 1648 \text{ kJ})$
- 2 O=O bonds: $(2 \times 498 = 996 \text{ kJ})$

Total energy to break bonds: $(1648 + 996 = 2644 \text{ kJ})$

Step 2: Form bonds in products:

- 2 C=O bonds in CO_2 : $(2 \times 799 = 1598 \text{ kJ})$
- 4 O-H bonds in $2 \text{ H}_2\text{O}$ molecules: $(4 \times 463 = 1852 \text{ kJ})$ (assuming O-H bond enthalpy is 463 kJ/mol)

Total energy released: $(1598 + 1852 = 3450 \text{ kJ})$

Step 3: Calculate (ΔH) :

$(\Delta H \approx \text{Energy to break} - \text{Energy to form} = 2644 - 3450 = -805 \text{ kJ})$

Result:

Approximate enthalpy change for the reaction is -805 kJ (exothermic).

Question What is the main concept behind thermochemistry in Pearson Chemistry?

Answer Thermochemistry focuses on the study of heat changes that occur during chemical reactions and physical processes, emphasizing concepts like enthalpy, heat capacity, and calorimetry. How do you calculate the enthalpy change for a reaction using Hess's Law? You add or subtract the known enthalpy changes of related reactions to find the overall enthalpy change for the target reaction, ensuring the reactions are combined appropriately to cancel out intermediates. What methods are commonly used to measure heat transfer in thermochemistry experiments? Calorimetry, particularly coffee cup and bomb calorimetry, are commonly used to measure heat transfer during chemical reactions by monitoring temperature changes in a controlled environment. How does bond enthalpy relate to the energy changes observed in thermochemistry? Bond enthalpy represents the energy required to break a specific bond in a molecule; differences in bond enthalpies between reactants and products help determine the overall enthalpy change of the reaction. What is the significance of standard enthalpy of formation in thermochemical calculations? Standard enthalpy of formation is the heat change when one mole of a compound forms from its elements in their standard states, serving as a reference point for calculating reaction enthalpies. How do endothermic and exothermic reactions differ in thermochemical terms? Endothermic reactions absorb heat from their surroundings, resulting in a positive enthalpy change, while exothermic reactions release heat, leading to a negative enthalpy change. What role does heat capacity play in calorimetry experiments? Heat capacity indicates how much heat is needed to raise the temperature of a substance by a certain amount; it's essential for calculating the heat transferred during reactions in calorimetry. How can you determine the enthalpy change of a reaction experimentally using calorimetry? By measuring the temperature change of a known quantity of reactants or products in a calorimeter and applying the heat capacity, you can calculate the heat transferred and thus the enthalpy change. Why is it important to consider the state (pressure, temperature) when discussing thermochemical data? Thermochemical data are state functions; the enthalpy change depends on the initial and final states. Consistency in pressure and temperature conditions ensures accurate

and comparable measurements.
